Abstract—The dynamics of a population distributed on a torus is described by an equation of the Kolmogorov–Petrovsky–Piskunov–Fisher type in the divergence form. The population is exploited by periodic harvesting of a constant distributed measurable fraction of its density. We prove that there exists a harvesting ratio maximizing the time-averaged income in kind, i.e., a ratio that provides an optimal stationary exploitation in the long run.

Keywords: distributed population, Kolmogorov–Petrovsky–Piskunov–Fisher equation, impulse control, optimal solution.
